

## Information Collection Engine Process Overview

The Information Collection Engine (ICE) uses SNMP scanning within the internal network only, via the standard SNMP port (UDP port 161).

- ICE Discovery and collection process summary:
- The ICE pings each IP address; if no valid response it assumes there is nothing listening at that IP address and moves to the next.
  - Assuming a valid ping response, the ICE then uses SNMP to retrieve a standard SNMP value from the device. If nothing is returned the ICE engine stops scanning.
  - If a valid SNMP response is received, the ICE attempts to get information from the public standard Printer MIB. If nothing is found then the ICE assumes this is a valid SNMP device, but not a printer/copier and ignores it.
  - If the device is a print device, the ICE scans the MIB data.
  - A temporary XML file is created containing the results of each device scan ready for transmission.
